(54) Title: AN INDUCIBLE METHOD FOR PRODUCTION OF RECOMBINANT ADENO-ASSOCIATED VIRUSES UTILIZING T7 POLYMERASE

(57) Abstract

Methods for efficient production of recombinant AAV are described. In one aspect, three vectors are introduced into a host cell. A first vector directs expression of T7 polymerase. A second vector carries rep and cap under the control of the T7 promoter. A third vector contains a rAAV cassette which contains a minigene flanked by AAV ITRs. In a second aspect, the host cell is stably transfected to contain a plasmid bearing one of the required vector components and the host cell is double transfected/infected.

AN INDUCIBLE METHOD FOR PRODUCTION OF RECOMBINANT  
ADENO-ASSOCIATED VIRUSES UTILIZING T7 POLYMERASE

Background of the Invention

Adeno-associated virus is a replication-  
5 deficient parvovirus, the genome of which is about 4.6 kb  
in length, including 145 nucleotide inverted terminal  
repeats (ITRs). The single-stranded DNA genome of AAV  
contains genes responsible for replication (rep) and  
formation of virions (cap).

10 When this nonpathogenic human virus infects a  
human cell, the viral genome integrates into chromosome  
19 resulting in latent infection of the cell. Production  
of infectious virus and replication of the virus does not  
occur unless the cell is coinfecting with a lytic helper  
15 virus such as adenovirus or herpesvirus. Upon infection  
with a helper virus, the AAV provirus is rescued and  
amplified, and both AAV and helper virus are produced.

AAV possesses unique features that make it  
attractive as a vector for delivering foreign DNA to  
20 cells. Various groups have studied the potential use of  
AAV in the treatment of disease states.

However, an obstacle to the use of AAV for  
delivery of DNA is the lack of highly efficient methods  
for encapsidation of recombinant genomes. See, R. Kotin,  
25 Hum. Gene Ther., 5:793-801 (1994). Furthermore, the rep  
gene product is toxic to cells and thus cannot be  
expressed at high levels. For example, previously known  
methods employ transfection of host cells with a rAAV  
genome which lacks rep and cap genes followed by co-  
30 infection with wild-type AAV and adenovirus. However,  
this method leads to unacceptably high levels of wild-  
type AAV. Incubation of cells with rAAV in the absence  
of contaminating wild-type AAV or helper adenovirus is  
associated with little recombinant gene expression. And,  
35 in the absence of the AAV rep gene product, integration  
is inefficient and not directed to chromosome 19.

Bacteriophage T7 RNA polymerase (T7 Pol) is the product of T7 gene 1, which can recognize its responsive promoter sequence specifically and exhibit a high transcriptase activity [M. Chamberlin et al, Nature, 5 228:227-231 (1970); J. Dunn and F. Studier, J. Mol. Biol., 166:447-535 (1983); and B. Moffatt et al, Cell, 49:221-227 (1987)]. It has been used for heterologous expression of proteins in *E. coli* [S. Tabor and C. Richardson, Proc. Natl. Acad. Sci. USA, 82:1074-1078 10 (1985); F. Studier and B. Moffatt, J. Mol. Biol., 189:113-130 (1986)], in recombinant vaccinia virus-infected eukaryotic cells [T. Fuerst et al, Proc. Natl. Acad. Sci. USA, 83:8122-8126 (1986); A. Ramsey-Ewing and B. Moss, J. Biol. Chem., 271:16962-16966 (1996)], and in 15 mammalian cells [A. Lieber et al, Nucl. Acids Res., 17:8485-8493 (1989)].

What is needed is an efficient method for production of rAAV which avoids the problems associated with rep toxicity for the packaging cell.

## 20 Summary of the Invention

The present invention provides an inducible method for efficient production of rAAV which makes use of T7 polymerase. T7 Pol is derived from lambda phage and its promoter is not active in mammalian cells. Thus, 25 expression of rep/cap can be controlled by placing these genes under control of the T7 promoter and providing the T7 Pol in trans or under the control of an inducible promoter. Thus, this method avoids the toxic effects of rep which rendered prior art methods of producing rAAV 30 inefficient. The method of the invention is particularly suitable for large scale production of rAAV, which is desired for rAAV vectors to be used in gene therapy.

In one aspect, the invention provides a method of producing rAAV which utilizes three vectors. A first

vector is capable of expressing T7 polymerase in the host cell following transfection or infection. A second vector comprises the AAV *rep* and *cap* genes under the control of T7 promoter sequences (T7/*rep/cap*). The third  
5 vector comprises a cassette containing 5' and 3' AAV inverted terminal repeats (ITRs) flanking a selected transgene. A host cell containing these three vectors is cultured under conditions which permit replication and packaging of a recombinant AAV, and the rAAV is  
10 recovered.

In another aspect, the invention provides a method in which a host cell is stably transfected with one of the three components of the system used in the triple infection system. The remaining components are  
15 introduced into the host cell, as described above.

In one embodiment, the invention provides method in which a vector containing T7/*rep/cap* and a vector containing a cassette comprising a selected minigene flanked by 5' and 3' AAV ITRs are introduced  
20 into a host cell expressing T7 polymerase. The host cell is then cultured under conditions which permit production of rAAV. In another embodiment, this invention provides a method which utilizes a host cell stably transfected with a plasmid containing T7/*rep/cap*. A vector  
25 containing T7 *pol* and a vector containing a cassette comprising 5' AAV inverse terminal repeat (ITR), a selected minigene, and 3' AAV ITR are introduced into the host cell. The host cell is cultured under conditions which permit production of rAAV. In still another  
30 embodiment, the invention provides a method which utilizes a host cell stably transfected with a rescuable rAAV cassette. A vector containing T7 *pol* and a vector containing T7/*rep/cap* are introduced into the host cell. The host cell is cultured under conditions which permit  
35 production of rAAV.

In yet another aspect, the present invention provides a method which utilizes a host cell stably transfected with two of the three components of the system used in the triple infection system. The  
5 remaining component is then introduced into the host cell, as described above.

In a further aspect, the present invention provides a method which utilizes a host cell stably transfected with the three components of the system used  
10 in the triple infection system. In this aspect, the T7 Pol is controlled by an inducible promoter.

In still a further aspect, the invention provides a rAAV produced according to the method of the invention.

15 Other aspects and advantages of the present invention are described further in the following detailed description of the preferred embodiments thereof.

#### Brief Description of the Drawings

Fig. 1 provides a schematic illustration of the  
20 construction of a recombinant adenovirus containing the T7 polymerase gene.

Fig. 2 provides a schematic illustration of the construction of a recombinant plasmid containing the AAV rep/cap genes under control of a T7 promoter.

25 Fig. 3 provides a schematic illustration of the construction of a recombinant adenovirus containing the rep/cap genes under control of a T7 promoter.

Fig. 4 provides a schematic illustration of the construction of a recombinant hybrid Ad/AAV virus.

#### 30 Detailed Description of the Invention

The invention provides an inducible method for efficient production of recombinant AAV vectors useful particularly for gene delivery and transfer.

Specifically, the invention provides methods of AAV production in which expression of the toxic but necessary rep gene is controlled by the T7 promoter.

Thus, in one aspect, the method of the invention for production of rAAV involves introducing into a host cell the AAV rep and cap genes under control of a T7 promoter, and a recombinant adeno-associated virus (rAAV) cassette containing a selected minigene flanked by AAV ITRs. Upon introduction of a gene encoding T7 pol, high level expression of rep protein from the T7/rep/cap construct is induced and cells may be grown on a large scale. When rep expression is desired, the cells are caused to express the T7 polymerase which acts on the T7 promoter. This facilitates the efficient replication and packaging of rAAV carrying a gene of interest.

A host cell may be triple transfected (or infected) with vectors containing the above elements. Alternatively, a host cell which expresses one or more of the required elements and may be transfected/infected with the remaining elements is utilized. In another alternative, a host cell is utilized which stably expresses all three elements of the system, and the T7 pol is placed under the control of an inducible promoter, which permits rep/cap expression to be controlled and the avoidance of toxic effects to the cell.

For each of the vector components used in the method of the invention, adenoviral constructs are currently preferred. However, using the information provided herein and known techniques, one of skill in the art could readily construct a different viral (adenoviral or non-adenoviral) or a plasmid vector which is capable of driving expression of the desired genes in the host cell. For example, although less preferred because of their inability to infect non-dividing cells, vectors

carrying the required elements of this system, e.g., the T7 polymerase, may be readily constructed using retroviruses. Therefore, this invention is not limited by the virus or plasmid selected for purposes of introducing the T7 pol, T7/rep/cap, or AAV cassette into the host cell. Desirably, at least one of the vectors is a virus which provides the necessary helper functions to enable packaging. Alternatively, the helper functions may be provided by a co-transfected adenovirus or herpesvirus. Suitable techniques for introducing these vectors into the host cell are discussed below and are known to those of skill in the art. As used herein, a "host cell" is any cell (cell line), preferably mammalian, which permits expression of the T7 pol and T7/rep/cap and packaging of the rAAV containing the cassette, under the conditions described herein. Suitable packaging cells are known, and may be readily selected by the skilled artisan.

A. *Triple Infection/Transfection*

As stated above, a host cell used for assembly and packaging of recombinant AAV may be transfected with plasmid vectors or infected with viral vectors containing the required components of the system.

1. *T7 Pol Vectors*

In a preferred embodiment, a first vector contains the T7 Pol gene under the control of a suitable promoter. In example 5 below, the nuclear localized T7 Pol gene is obtained from a publicly available plasmid [M. Strauss, Nucleic Acid Res., 17:8485-8493 (1989)]. However, the gene may alternatively be obtained from other commercial and academic sources, including the American Type Culture Collection (pTF7-3, Accession No. 484944). See, also GenBank accession number M30308. Desirably, the T7 pol

gene is linked to a nuclear localization signal, such as that described in Dunn, Gene, 68:259-266 (1988), using conventional techniques.

Desirably, T7 Pol is under the control of a cytomegalovirus (CMV) immediate early promoter/enhancer [see, e.g., Boshart et al, Cell, 41:521-530 (1985)]. However, other suitable promoters may be readily selected by one of skill in the art. Useful promoters may be constitutive promoters or regulated (inducible) promoters, which will enable control of the amount of the transgene to be expressed. For example, another suitable promoter includes, without limitation, the Rous sarcoma virus LTR promoter/enhancer. Still other promoter/enhancer sequences may be selected by one of skill in the art.

In addition, the vector also includes other conventional regulatory elements necessary to drive expression of T7 Pol in a cell transfected with the vector. Such regulatory elements are known to those of skill in the art.

## 2. T7/Rep/Cap Vectors

The second vector component of this system contains the *rep* and *cap* genes under control of a T7 promoter. The *rep* and *cap* genes can be obtained from a variety of known sources. See, e.g., T. Shenk, J. Virol., 61:3096-3101 (1987), which provides the AAV2 genome within the plasmid psub201; E. W. Lusby et al, J. Virol., 41:518-526 (1982) and J. Smuda and B.J. Carter, Virology, 184:310-318 (1991).

Similarly, the T7 promoter sequences [J. J. Dunn and F.W. Studier, J. Mol. Biol., 166:477-535 (1983)] may be obtained from a variety of commercial and academic sources. In a preferred embodiment, the vector further contains the sequence of untranslated region (UTR) of encephalomyocarditis (EMCV) downstream of the T7

promoter. The inventors believe this sequence increases expression of the gene 5- to 10-fold.

In addition, the vector also includes conventional regulatory elements necessary to drive  
5 expression of the rep/cap in a cell transfected with the vector. Such regulatory elements are known to those of skill in the art.

### 3. rAAV Cassette (Template)

The third vector component contains a  
10 rAAV cassette containing a minigene flanked by AAV ITRs. As discussed in more detail below, such a minigene contains a suitable transgene, a promoter, and other regulatory elements necessary for expression of the transgene.

15 The AAV sequences employed are preferably limited to the cis-acting 5' and 3' inverted terminal repeat (ITR) sequences [See, e.g., B. J. Carter, in "Handbook of Parvoviruses", ed., P. Tijsser, CRC Press, pp.155-168 (1990)]. Desirably, substantially the  
20 entire 143 bp sequences encoding the ITRs are used in the vectors. Some degree of minor modification of these sequences is expected to be permissible for this use. The ability to modify these ITR sequences is within the skill of the art. See, e.g., texts such as Sambrook et  
25 al, "Molecular Cloning. A Laboratory Manual.", 2d edit., Cold Spring Harbor Laboratory, New York (1989). Alternatively, it may be desirable to use functional fragments of the ITRs. Such fragments may be determined by one of skill in the art.

30 The AAV ITR sequences may be obtained from any known AAV, including presently identified human AAV types. Similarly, AAVs known to infect other animals may also be employed in the vector constructs of this invention. The selection of the AAV is not anticipated  
35 to limit the following invention. A variety of AAV

strains, types 1-4, are available from the American Type Culture Collection or available by request from a variety of commercial and institutional sources. In the following exemplary embodiment an AAV-2 is used for  
5 convenience.

The 5' and 3' AAV ITR sequences flank a minigene which is made up of a selected transgene sequence and associated regulatory elements. The transgene sequence of the vector is a nucleic acid  
10 sequence heterologous to the AAV sequence, which encodes a polypeptide or protein of interest. The transgene is operatively linked to regulatory components in a manner which permits transgene transcription.

The composition of the transgene  
15 sequence will depend upon the use to which the resulting vector will be put. For example, one type of transgene sequence includes a reporter sequence, which upon expression produces a detectable signal. Such reporter sequences include without limitation an *E. coli* beta-galactosidase (*LacZ*) cDNA, an alkaline phosphatase gene  
20 and a green fluorescent protein gene. These sequences, when associated with regulatory elements which drive their expression, provide signals detectable by conventional means, e.g., ultraviolet wavelength  
25 absorbance, visible color change, etc. A more preferred transgene sequence includes a therapeutic gene which expresses a desired gene product in a host cell. These therapeutic nucleic acid sequences typically encode products which may be administered to a patient *in vivo*  
30 or *ex vivo* to replace or correct an inherited or non-inherited genetic defect or treat an epigenetic disorder or disease. The selection of the transgene sequence is not a limitation of this invention.

In addition to the major elements identified above, the minigene also includes conventional regulatory elements necessary to drive expression of the transgene in a cell transfected with the vector carrying the AAV cassette. Thus the minigene contains a selected promoter which is linked to the transgene and located within the minigene, between the AAV ITR sequences of the vector.

Selection of the promoter which mediates expression of the transgene is a routine matter and is not a limitation of the vector. Useful promoters include those which are discussed above in connection with the first vector component.

The minigene will also desirably contain heterologous nucleic acid sequences including sequences providing signals required for efficient polyadenylation of the transcript and introns with functional splice donor and acceptor sites. A common poly-A sequence which is employed in the exemplary vectors of this invention is that derived from the papovavirus SV-40. The poly-A sequence generally is inserted following the transgene sequences and before the 3' AAV ITR sequence. A common intron sequence is also derived from SV-40, and is referred to as the SV-40 T intron sequence. A minigene of the present invention may also contain such an intron, desirably located between the promoter/enhancer sequence and the transgene. Selection of these and other common vector elements are conventional and many such sequences are available [see, e.g., Sambrook et al, and references cited therein].

The rAAV vector containing the AAV ITRs flanking the minigene may be carried on a plasmid backbone and used to transfect a selected host cell or may be flanked by viral sequences (e.g., adenoviral sequences) which permit it to infect the selected host

cell. Suitable Ad/AAV recombinant viruses may be produced in accordance with known techniques. See, e.g., WO 96/13598, WO 95/23867, and WO 95/06743, which are incorporated by reference herein.

5                   B.    *Double Infection/Transfection*

A cell line which stably expresses T7 pol may be constructed, and then double transfected (or infected) with a vector containing T7/rep/cap and a vector containing a rAAV cassette, as illustrated in the following table (Inf = infection and Txf = transfection).

|               | <u>T7 rep/cap</u> | <u>rAAV</u> |
|---------------|-------------------|-------------|
| System A      | Inf               | Inf         |
| System B      | Inf               | Txf         |
| System C      | Txf               | Inf         |
| 15   System D | Txf               | Txf         |

Alternatively, a cell line stably transfected with T7 rep/cap may be double transfected (infected) with a vector carrying T7 pol and a vector carrying the rAAV cassette, as illustrated in the following table.

|               | <u>T7 Pol</u> | <u>rAAV</u> |
|---------------|---------------|-------------|
| System E      | Inf           | Inf         |
| System F      | Inf           | Txf         |
| System G      | Txf           | Inf         |
| 25   System H | Txf           | Txf         |

In still another alternative, a cell line which contains a rescuable rAAV cassette may be double transfected (infected) with a vector containing T7 Pol and a vector containing T7/rep/cap, as illustrated in the following table.

|               | <u>T7 Pol</u> | <u>T7 rep/cap</u> |
|---------------|---------------|-------------------|
| System I      | Inf           | Inf               |
| System J      | Inf           | Txf               |
| System K      | Txf           | Inf               |
| 35   System L | Txf           | Txf               |

The plasmid and viral vectors used in double transfection/infection steps are as described above in connection with the triple transfection and/or infection system.

5                   A stable cell line of the invention can be produced by transfection of a desired cell, e.g., 293 cells or other packaging cell lines expressing required adenoviral genes, with a plasmid containing the desired gene, e.g., T7 Pol, using conventional techniques and  
10                   selected via an accompanying resistant marker gene. Depending upon whether inducible or constitutive expression is desired, an appropriate promoter may be selected. For example, if a host cell inducibly expressing T7 Pol is desired, the cell may be transfected  
15                   with a plasmid containing T7 Pol under control of a metallothionein promoter. Alternatively, if a host cell constitutively expressing T7 Pol is desired, it may be inserted under control of a RSV or CMV promoter. Similar techniques may be used for providing a host cell  
20                   containing the T7/rep/cap and a host cell containing a rescuable rAAV. The examples below describe production of stable cell lines. However, one of skill in the art could readily produce such cell lines using other conventional techniques. See, generally, Ausubel et al,  
25                   Current Protocols in Molecular Biology (Wiley Interscience 1987).

#### C. *Single Infection/Transfection*

                  A cell line which stably expresses two of the components of this system may be constructed, and  
30                   then transfected (or infected) with a vector containing the remaining component of the system, as described above. For example, using the techniques described herein, a cell line is utilized which is stably transfected with the T7/rep/cap and a rescuable rAAV.  
35                   The cell line is then transfected or infected with a

vector containing the T7 pol. As another example, the cell line is stably transfected with the T7 pol and a rescuable rAAV. The cell line is then transfected or infected with a vector containing the T7 rep/cap.

5                   D.    *Cell Line Containing T7 Pol, rAAV and T7/rep/cap*

A cell line which stably expresses all three of the components of this system may be constructed and utilized in the method of the invention. Using known techniques, a suitable packaging cell line is constructed which contains the rAAV, the T7/rep/cap and the T7 pol. In this embodiment, the T7 Pol is placed under the control of an inducible promoter. Suitable inducible promoters are known to those of skill in the art and are discussed herein. For example, T7 Pol may be placed under control of a metallothionein promoter. In this manner, expression of the T7 Pol, and thus the rep/cap, which are under control of the T7 promoter can be regulated and toxic effects to the cell avoided.

20                   E.    *Production of Vectors and rAAV*

Assembly of the selected DNA sequences of the adenovirus, AAV and the reporter genes or therapeutic genes and other vector elements into the vectors described above utilize conventional techniques. Such techniques include cDNA cloning such as those described in texts [Sambrook et al, cited above], use of overlapping oligonucleotide sequences of the adenovirus or AAV genome, polymerase chain reaction, and any suitable method which provides the desired nucleotide sequence.

Whether using the three vector system, or stably infected cells, introduction of the vectors into the host cell is accomplished using known techniques. Where appropriate, standard transfection and co-transfection techniques are employed, e.g.,  $\text{CaPO}_4$

transfection techniques using the complementation human embryonic kidney (HEK) 293 cell line (a human kidney cell line containing a functional adenovirus E1a gene which provides a transacting E1a protein). Other conventional methods employed in this invention include homologous recombination of the viral genomes, plaquing of viruses in agar overlay, methods of measuring signal generation, and the like.

Following infection/transfection, the host cell is then cultured under standard conditions, to enable production of the rAAV. See, e.g., F. L. Graham and L. Prevec, Methods Mol. Biol., 7:109-128 (1991). Desirably, once the rAAV is identified using conventional techniques, it may be isolated using standard techniques and purified.

These examples illustrate the preferred methods of the invention. These examples are illustrative only and do not limit the scope of the invention.

#### Example 1 - Construction of a T7 Pol Adenovirus

Figure 1 provides a schematic of the construction of the recombinant adenovirus carrying the T7 polymerase.

The plasmid pMTT7N was obtained from Dr. Michael Strauss [A. Lieber et al, Nucl. Acids Res., 17:8485-8493 (1989)]. pMTT7N contains a N-terminal nuclear location signal of SV40 large T antigen fused to the T7 Pol gene (T7N Pol) which is linked to the polyadenylation sequence of SV40. Expression is driven by the inducible mouse metallothionein promoter.

The pMTT7N plasmid DNA was digested with BglII and PvuII restriction enzymes and the fragments separated on an agarose gel. The BglII/PvuII T7 Pol DNA fragment was ligated to the BglII/EcoRV cleaved vector pAd.CMV.link.1 to form pAd.CMV.T7N. pAd.CMV.link.1 is a

plasmid containing the adenoviral sequences 0 to 16 map units deleted of E1a and E1b into which a CMV promoter-polylinker cassette was cloned. This is described in X. Ye et al, J. Biol. Chem., 271:3639-3646 (1996).

In pAd.CMV.T7N, the expression unit of T7 Pol is directed by the CMV promoter. The promoter for the T7 Pol gene is linked to a PolyA tail as a cassette within the sequence of adenovirus 0-1 map unit (mu) and 9-16 mu. The pAd.CMV.T7N is linearized by Nhe I digestion and co-transfected with Cla I linearized Addel327 backbone using Cellphate kit (Pharmacia). Approximately 1 week post-transfection, the T7 Pol adenovirus can be isolated from the plaques for further purification.

#### 15 Example 2 - Cell Lines Expressing T7 Pol

A cell line stably expressing T7 Pol is established by co-transfection of plasmids pMTT7N and pMTCB6+ (which provides a selective marker) [K. H. Choo et al, DNA, 5:529-538; Eur. J. Biochem., 174:417-424] into 293 cell at a ratio of 10:1 using calcium phosphate precipitation [F. Graham and A. van der Eb, Virology, 52:456-467 (1973)]. Colony cloning is carried out by Geneticin selection at a concentration of 1 mg/ml. Each clone obtained is transfected with pT7 rep/cap plasmid [see, Example 3 below] and analyzed for its ability to induce the expression of Rep protein upon induction by supplementation with Zn<sup>++</sup>.

To establish a stable cell line that constitutively expresses the T7 Pol, the T7N Pol (obtained by BglIII/PvuII digestion of pMTT7N, as described above) was subcloned downstream of RSV promoter at the cloning sites of BamHI and PvuII in the vector of pEBVhis [Invitrogen]. The resulting plasmid, designated pEBVhisT7N, was transfected into 293 cells and selected

with Hygromycin at a concentration of 400 µg/ml. Each positive clone is analyzed for the presence of T7 Pol by its ability to produce expression of T7-LacZ or T7-rep/cap in cells transfected with these plasmids.

5    Example 3 - Production of T7 rep/cap Adenovirus

The production of this recombinant adenoviral vector is illustrated schematically in Figs. 2 and 3.

A.    *Plasmid Construction*

10    The plasmid pTM1 [B. Moss et al, Nature, 348:91-92 (1990)], designed for expressing genes under control of the T7 promoter/EMCV UTR (untranslated region of encephalomyocarditis), was used as the vector for expressing AAV rep/cap. The entire coding sequence of rep/cap was separated into two portions by the unique  
15    SacI site and subcloned into the pTM1 plasmid as described below.

Because there is no appropriate restriction enzyme existing between the initiation site of rep and its natural promoter, p5, the left end of the  
20    rep sequence (N-rep) was first amplified by PCR. The sequence of the upper primer was SEQ ID NO:2: TATTTAAGCCCGAGTGAGCT (from position of 255 to 274) which introduced a nucleotide substitution A->T at position 274 (underlined). A SacI site was then generated to permit  
25    the cloning of N-rep into pTM1 and in-frame expression of Rep protein from the EMCV UTR preferred initiation site (within the NcoI site). The PCR product (739 bp in length) was directly cloned into pCR2.1 vector (Invitrogen) and named pCR-N-rep.

30    The pTM-1 plasmid was digested with SacI and Stu I restriction enzymes and ligated with a 3.7 kb SacI/SnaBI fragment from psub201 [Samulski et al, J. Virol., 61:3096-3101 (1987)] containing the right end of the AAV genome (without ITR sequence), i.e., the c-

terminal portion of rep and full-length cap sequence.  
This T7 promoter-driven rep/cap construct is named pT7-c-  
rep/cap.

The first 535 bp sequence of rep was  
5 removed from the pCR-N-Rep plasmid by SacI digestion and  
subcloned into pT7-C-rep/cap, which has similarly been  
digested with SacI and subjected to alkaline phosphatase  
treatment to prevent self-ligation of the vector. The  
final construct was named pT7 rep/cap which contains the  
10 full length coding sequence of rep/cap downstream of T7  
promoter/EMCV UTR, followed by the T7 terminating  
sequence.

B. *Production T7 rep/cap Adenovirus*

pAd.link is a construct similar to  
15 pAd.CMV.link, a plasmid containing the adenoviral  
sequences 0 to 16 map units deleted of E1a and E1b as  
described in the other adenovirus vectors into which a  
CMV promoter-polylinker cassette was cloned and described  
in X. Ye et al, J. Biol. Chem., 271:3639-3646 (1996).  
20 However, pAd.link contains no CMV promoter or polyA tail  
sequence.

The entire region including the T7  
promoter, EMCV UTR, rep/cap and T7 terminating sequence  
was excised from pT7 rep/cap by digestion with ClaI and  
25 EagI, and then subcloned into the adenoviral sequences of  
pAd.link, which had previously been subjected to  
ClaI/SalI digestion, after filling in the sticky ends of  
EagI and SalI by Klenow polymerase. The resulting  
plasmid is designated pAd.T7 rep/cap.

30 The pAd.T7 rep/cap is co-transfected with  
the ClaI linearized Ad.del327 backbone DNA into 293 cell  
for the generation of T7 rep/cap adenovirus.

Example 4 - Cell Line Expressing rep/cap

A cell line stably transfected with pT7 rep/cap is established by transfection of pMTCB6+ into 293 cell at ratio of 10:1 and selected with Geneticin. Each clone is analyzed for the presence of rep protein by transfection with T7 Pol expressing plasmid.

Example 5 - Production of Recombinant AAV Hybrid Vector

Plasmid pAV.CMVLacZ serves as a template for rAAV to be replicated and packaged in the presence of AAV non-structural and capsid proteins.

Plasmid AV.CMVLacZ is a rAAV cassette in which rep and cap genes are replaced with a minigene expressing  $\beta$ -galactosidase from a CMV promoter. The linear arrangement of AV.CMVLacZ includes:

- (a) the 5' AAV ITR (bp 1-173) obtained by PCR using pAV2 [C. A. Laughlin et al, Gene, 23: 65-73 (1983)] as template [nucleotide numbers 365-538 of SEQ ID NO:1];
- (b) a CMV immediate early enhancer/promoter [Boshart et al, Cell, 41:521-530 (1985); nucleotide numbers 563-1157 of SEQ ID NO:1],
- (c) an SV40 intron (nucleotide numbers 1178-1179 of SEQ ID NO:1),
- (d) *E. coli* beta-galactosidase cDNA (nucleotide numbers 1356 - 4827 of SEQ ID NO:1),
- (e) an SV40 polyadenylation signal (a 237 BamHI-BclI restriction fragment containing the cleavage/poly-A signals from both the early and late transcription units; nucleotide numbers 4839 - 5037 of SEQ ID NO:1) and
- (f) 3'AAV ITR, obtained from pAV2 as a SnaBI-BglII fragment (nucleotide numbers 5053 - 5221 of SEQ ID NO:1).

Where desired, the LacZ gene can be replaced with a desired therapeutic or other transgene for the purpose of generating new rAAV. See, Fig. 4. The sequence including CMV directed LacZ reporter cassette in  
5 between two AAV ITR sequences is excised from pAV.CMV.LacZ by PvuII digestion. This fragment is ligated with the EcoRV treated pAd.link to generate the plasmid pAd.AV.CMVLacZ. This plasmid is co-transfected with ClaI linearized Addel327 backbone DNA to generate an  
10 adeno-rAAV hybrid virus.

Example 6 - Cell line containing rescuable, integrated rAAV template

293 cells are transfected/infected with pAV.CMVLacZ/rAAV Ad hybrid virus to generate cell line  
15 that has incorporated rAAV, as determined by analysis of the genomic DNA by Southern blot. The clone is examined for the rescue of rAAV template by transfection/infection with rep/cap expressing constructs.

Numerous modifications and variations of the  
20 present invention are included in the above-identified specification and are expected to be obvious to one of skill in the art. Such modifications and alterations to the processes of the present invention are believed to be encompassed in the scope of the claims appended hereto.

## (2) INFORMATION FOR SEQ ID NO:2:

- (i) SEQUENCE CHARACTERISTICS:
  - (A) LENGTH: 20 base pairs
  - (B) TYPE: nucleic acid
  - (C) STRANDEDNESS: single
  - (D) TOPOLOGY: unknown

(ii) MOLECULE TYPE: other nucleic acid

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:2:

TATTTAAGCC CGAGTGAGCT

20

What is claimed is:

1. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:
  - (a) introducing into a selected host cell a first vector comprising T7 polymerase under control of sequences which drive expression thereof,
    - a second vector comprising AAV rep and cap genes under control of T7 promoter sequences which drive expression of rep and cap; and
    - a third vector comprising from 5' to 3', a cassette consisting essentially of a 5' AAV inverted terminal repeat (ITR), a selected minigene, and a 3' AAV ITR;
  - (b) culturing the host cell under conditions which permit replication and packaging of recombinant AAV; and
  - (c) recovering the recombinant AAV.
2. The method according to claim 1 wherein at least one of the vectors is an adenovirus and the host cell is a 293 cell.
3. The method according to claim 1 wherein the first vector is a recombinant adenovirus.
4. The method according to claim 1 wherein the second vector is a recombinant adenovirus.
5. The method according to claim 1 wherein the third vector further comprises adenoviral sequences flanking the cassette.

6. The method according to any of claims 1 to 5 wherein the minigene contains a transgene which is a marker gene.

7. The method according to claim 6 wherein the minigene contains a transgene which is a therapeutic gene.

8. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:

(a) providing a host cell which expresses T7 polymerase;

(b) introducing into the host cell a first vector which comprises AAV *rep* and *cap* genes under control of T7 promoter sequences;

(c) introducing into the host cell a second vector comprising a cassette consisting essentially of 5' AAV inverse terminal repeat (ITR), a selected minigene, and 3' AAV ITR; and

(d) culturing the host cell under conditions which permit replication and packaging of a recombinant AAV.

9. The method according to claim 8 wherein step (b) comprises the step of transfecting the host cell with a vector comprising the T7 promoter and the AAV *rep* and *cap* genes.

10. The method according to claim 8 wherein step (b) comprises the step of infecting the host cell with a recombinant adenovirus comprising the T7 promoter sequences, and the AAV *rep* and *cap* genes.

11. The method according to claim 8 wherein step (c) comprises transfecting the host cell with a vector comprising the cassette.

12. The method according to claim 8 wherein step (c) comprises infecting the host cell with a recombinant adenovirus comprising the cassette flanked by adenovirus sequences.

13. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:

(a) providing a host cell stably transfecting with AAV *rep* and *cap* genes under control of T7 promoter sequences;

(b) introducing into the host cell a vector comprising T7 polymerase;

(c) introducing into the host cell with vector comprising a cassette consisting essentially of a 5' AAV inverse terminal repeat (ITR), a selected minigene, and a 3' AAV ITR; and

(d) culturing the host cell under conditions which permit replication and packaging of a recombinant AAV.

14. The method according to claim 13 wherein step (b) comprises the step of transfecting the host cell with a vector comprising the T7 polymerase gene.

15. The method according to claim 13 wherein step (b) comprises the step of infecting the host cell with a recombinant adenovirus comprising the T7 polymerase gene under control of regulatory sequences controlling expression thereof.

16. The method according to claim 13 wherein step (c) comprises the step of transfecting the host cell with a vector comprising the cassette.

17. The method according to claim 13 wherein step (c) comprises the step of infecting the host cell with a recombinant adenovirus comprising the cassette flanked by adenovirus sequences.

18. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:

(a) providing a host cell comprising a cassette consisting essentially of 5' AAV inverse terminal repeats (ITR), a selected minigene, and a 3' AAV ITR;

(b) introducing into the host cell a vector comprising AAV rep and cap genes under control of T7 promoter sequences;

(c) introducing into the host cell a vector comprising the T7 polymerase; and

(d) culturing the host cell under conditions which permit replication and packaging of a recombinant AAV.

19. The method according to claim 18 wherein step (b) comprises the step of transfecting the host cell with a plasmid vector.

20. The method according to claim 18 wherein step (b) comprises the step of infecting the host cell with a recombinant adenoviral vector.

21. The method according to claim 18 wherein step (c) comprises the step of transfecting the host cell with a plasmid vector containing the T7 polymerase under control of regulatory sequences which direct expression thereof.

22. The method according to claim 18 wherein step (c) comprises the step of infecting the host cell with a recombinant adenovirus comprising the T7 polymerase under control of regulatory sequences which direct expression thereof.

23. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:

(a) providing a host cell stably transfected with a cassette consisting essentially of 5' AAV inverse terminal repeats (ITR), a selected minigene, and a 3' AAV ITR and a plasmid comprising AAV rep and cap genes under control of T7 promoter sequences;

(b) introducing into the host cell a vector comprising the T7 polymerase; and

(c) culturing the host cell under conditions which permit replication and packaging of a recombinant AAV.

24. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of;

(a) providing a host cell stably transfected with a cassette consisting essentially of 5' AAV inverse terminal repeats (ITR), a selected minigene, and a 3' AAV ITR and a plasmid comprising T7 polymerase;

(b) introducing into the host cell a vector comprising AAV rep and cap genes under control of T7 promoter sequences; and

(c) culturing the host cell under conditions which permit replication and packaging of a recombinant AAV.

25. A method for production of recombinant adeno-associated virus (AAV) comprising the steps of:

- (a) providing a host cell stably transfected with
  - (i) a cassette consisting essentially of 5' AAV inverse terminal repeats (ITR), a selected minigene, and a 3' AAV ITR;
  - (ii) a plasmid comprising T7 polymerase under control of sequences which regulate expression thereof, said sequences comprising an inducible promoter; and
  - (iii) a plasmid AAV *rep* and *cap* genes under control of T7 promoter sequences; and
- (b) inducing expression of said T7 promoter.

26. A recombinant adenovirus produced according to the method of any one of claims 1 - 25.

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 97/15716

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N15/86 C12N7/01

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category | Citation of document, with indication, where appropriate, of the relevant passages  | Relevant to claim No. |
|----------|---|-----------------------|
| X        | LEONARD, C. J. ET AL: "Cloning, expression, and partial purification of Rep78: an adeno - associated virus replication protein"<br>VIROLOGY (1994), 200(2), 566-73 CODEN: VIRLAX; ISSN: 0042-6822, 1994, XP002052542<br>see the whole document<br>--- | 26                    |

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"8" document member of the same patent family
